Alcohol-attributable injuries in the WHO European Region

**Web annex – data sources and methods
underlying the 2019 estimates**

Abstract

This web annex presents detailed country-specific estimates of alcohol-attributable injury mortality and disability in the WHO European Region, including age-standardized alcohol-attributable death rates, the proportion of injury deaths caused by alcohol and breakdowns by major injury categories. It also provides information on the data sources and methods used for the summary report Alcohol-attributable injuries in the WHO European Region: Overview of key findings based on 2019 data. By offering granular and comparable national data, this resource supports cross-country analysis and helps inform targeted planning, monitoring and evaluation of alcohol-attributable injury prevention policies.

Keywords: ALCOHOL DRINKING; INJURIES; PREVENTION AND CONTROL; PUBLIC HEALTH; VIOLENCE

Methodology for modelling alcohol-attributable burden of injuries

The annex describes the methodology underlying the short report Alcohol-attributable injuries in the WHO European Region: Overview of key findings based on 2019 data (1) and follows the standard WHO methodology used for regular updates of the WHO Global Health Observatory (2).

Estimating the number of deaths of drivers resulting from motor vehicle accidents

Estimates of motor vehicle deaths were stratified into those involving the driver and those involving others, using Formula S.1. This method estimates the number of deaths (D) among drivers (d) using the fraction (F) of injury events in a country that occurred among drivers by sex (indexed by i) and age (indexed by p, including people 15 years of age and older). These fractions were based on data obtained from the WHO road traffic deaths database (1). The method of estimating the number of road injuries involving drivers assumed that all motor vehicle accident injuries to drivers occurred among people aged 15 years or older (i.e. all road injuries sustained by people 0 to 14 years of age were determined to affect people other than the driver). For countries where data were not available, the fractions of injuries among drivers and among people other than the driver were imputed as the global burden of disease regional averages. To estimate the number of years of life lost (YLL), years lived with disability (YLD), and disability adjusted life years (DALYs) lost among drivers, the fraction of deaths among drivers compared to all road deaths (by age and sex) were used. All other road deaths, YLLs, YLDs and DALYs lost affected people other than the driver.

$$Dd_{p,i} = \frac{F_i \cdot F_p \cdot \sum_{p=1}^{pn} \sum_{i=1}^{in} D_{p,i}}{D_{p,i}} \quad \text{Formula S.1}$$

Estimating the population-attributable fractions for injuries

The fractions of injuries attributable to alcohol consumption were estimated according to formulas S.2a and S.2b. These formulae incorporate the PFD and PCD combined with the corresponding RRs. Formula S.2b accounts for the patterns of alcohol consumption (i.e. the prevalence of current drinkers who engage in heavy episodic drinking (HED) (PHED) and who do not engage in HED (PNHED)).

$$PAF = \frac{P_{FD} (RR_{FD} - 1) + P_{CD} (RR_{CD} - 1)}{P_{FD} (RR_{FD} - 1) + P_{CD} (RR_{CD} - 1) + 1} \quad \text{Formula S.2a}$$

$$\begin{aligned} &P_{FD} (RR_{FD} - 1) \\ &= \int_{>0}^{60} P_{NHED}(x) RR_{NHED}(x) dx + \int_{>0}^{60} P_{HED}(x) RR_{HED}(x) dx \\ &+ \int_{60}^{150} P_{HED}(x) RR_{HED}(x) dx - P_{CD} \end{aligned} \quad \text{Formula S.2b}$$

Estimating the population-attributable fraction for road injuries sustained by people other than the driver

The PAFs for road injuries to people other than the driver (nd) were estimated in accordance with Formula S.3. Formula S.3 is based on the country-, sex- (indexed by p), and age- (indexed by i) specific deaths (D) and PAFs for road injuries affecting the driver. This method has multiple assumptions and limitations. Firstly, this method assumes that road injuries involving an intoxicated driver involve an equal number of passengers, as do accidents involving non-intoxicated drivers. Secondly, this method assumes that the distribution of the ages of passengers affected by road injuries involving intoxicated drivers is the same as the distribution of the ages of passengers affected by road injuries not involving intoxicated drivers. Lastly, this method does not account for non-intoxicated drivers killed or injured by intoxicated drivers.

Formula S.3

$$PAF_{nd} = \frac{\sum_{p=1}^{pn} \sum_{i=1}^{in} D_{p,i} \cdot PAF_{p,i}}{\sum_{p=1}^{pn} \sum_{i=1}^{in} D_{p,i}}$$

Modelling alcohol consumption for the estimation of alcohol-attributable mortality and morbidity

Alcohol consumption was modelled based on (i) the prevalence of different drinking statuses (current drinkers, former drinkers, lifetime abstainers), (ii) the average daily volume of alcohol consumption among current drinkers (measured in grams of ethanol per day), and (iii) the prevalence of HED (defined as drinking 60 grams or more of pure alcohol on one occasion in the past month among current drinkers). Data on alcohol consumption (drinking status and amount consumed by current drinkers) and binge drinking were obtained from the study by Manthey et al. (2). Data on drinking status and HED were available by year, age group (15–19, 20–24, 25–34, 35–49, 50–64, and 65 years of age and older), and sex.

The amount of alcohol consumed by current drinkers was modelled based on (i) per capita consumption of alcohol (obtained from the study by Manthey et al. (2)), (ii) age-specific prevalence of alcohol consumption, (iii) country- and year-specific estimates of relative average alcohol consumption by age and sex (obtained from the study by Manthey et al. (2)), and (iv) year-, sex- and age-specific population estimates.

When modelling the alcohol consumed by current drinkers, the per capita consumption of alcohol was adjusted using a correction factor of 0.8. This correction factor was used to account for (i) alcohol that was not consumed, and (ii) the underreporting of alcohol consumption in medical observation studies from which the RR estimates used in this study were obtained. (3) A study by Stockwell and colleagues found that cohort studies of the relationship between alcohol consumption and all-cause mortality had a coverage rate (when compared to per capita consumption) of 61.71% (4). The adjustment of survey data can be justified by the observation that the underreporting of alcohol consumption in medical epidemiology studies (5–7) is much less than in population surveys; population-level surveys underestimate alcohol consumption because, on average, such surveys ask many fewer questions that are used to measure alcohol consumption compared to the number of such questions asked in medical epidemiology studies (5–7). Furthermore, the undercoverage of population surveys is also affected by recruitment biases

(8). The method used to model alcohol consumption among current drinkers assumes that the undercoverage of alcohol consumption is constant by age and sex.

Average daily alcohol consumption among current drinkers was modelled using a Gamma distribution in accordance with the methodology outlined by Rehm et al. (9) and Kehoe et al. (10). This methodology was developed using data from over 60 individual surveys conducted in both developing and developed countries. Firstly, this method assumes that the average daily amount of alcohol consumed among current drinkers can be accurately modelled using a Gamma distribution, which was the case in the surveys examined by both Rehm and Kehoe and their respective colleagues. Secondly, this method assumes that the standard deviation of the Gamma distribution of alcohol consumption can be predicted on the basis of the mean consumption of alcohol. Both Rehm and Kehoe and their respective colleagues observed a strong correlation between the mean and the standard deviation of the Gamma distribution (an r of 0.971). Therefore, based on the mean alcohol consumed (μ) by age and sex, the standard deviation (σ) was estimated according to Formula S.4 (the coefficient of sex is 1 for women and 0 for men in Formula S.4)

$$\hat{\sigma}_{shifted} = (1.171 + 0.087 * sex) * \hat{\mu}_{shifted}$$

The WHO Regional Office for Europe

The World Health Organization (WHO) is a specialized agency of the United Nations created in 1948 with the primary responsibility for international health matters and public health. The WHO Regional Office for Europe is one of six regional offices throughout the world, each with its own programme geared to the particular health conditions of the countries it serves.

Member States

Albania	Greece	Portugal
Andorra	Hungary	Republic of Moldova
Armenia	Iceland	Romania
Austria	Ireland	Russian Federation
Azerbaijan	Israel	San Marino
Belarus	Italy	Serbia
Belgium	Kazakhstan	Slovakia
Bosnia and Herzegovina	Kyrgyzstan	Slovenia
Bulgaria	Latvia	Spain
Croatia	Lithuania	Sweden
Cyprus	Luxembourg	Switzerland
Czechia	Malta	Tajikistan
Denmark	Monaco	Türkiye
Estonia	Montenegro	Turkmenistan
Finland	Netherlands (Kingdom of the)	Ukraine
France	North Macedonia	United Kingdom
Georgia	Norway	Uzbekistan
Germany	Poland
